

**Nucleotide Sequences of the Nucleocapsid (NP) and Phosphoprotein (P) Genes of a Malaysian Velogenic Newcastle Disease Virus Strain AF2240 and the Production of the NP and P Proteins in *Escherichia coli***

**Field of the Invention**

The present invention relates to nucleotide sequences encoding the nucleocapsid (NP) protein and phosphoprotein (P) of Newcastle disease virus (NDV) strain AF2240, and the production of the corresponding proteins with recombinant plasmids bearing the nucleotide sequences in *Escherichia coli*.

**Description of the Prior Art**

Newcastle disease virus (NDV) is the prototype of avian paramyxovirus, which causes a highly contagious disease known as Newcastle disease (ND) in many avian species. This disease is of great economic importance requiring control by vaccination or quarantine with slaughter of all birds in confirmed outbreaks, resulting in substantial losses in the poultry industry worldwide. Therefore, development of an improved vaccine and also a rapid and sensitive diagnostic test are greatly desired by the poultry industry.

A Malaysian heat resistant NDV strain AF2240, which causes 100% mortality in susceptible chicken flocks has been reported by Abdul Rahman *et al.* (1976) and Lai, C.M. (1985). Further studies by Idris *et al.* (1993) revealed that the thermostabilities of haemagglutination and neuraminidase activities of this AF2240 strain were found to be higher than those of other strains. The basis giving rise to these unique features is still unknown. However a comprehensive understanding of the viral proteins would provide some solutions and useful information for the development of heat stable recombinant vaccines and diagnostic tests.

The genome of NDV is a linear, non-segmented, single-stranded negative sense RNA with a molecular weight of  $5.2-5.7 \times 10^6$  Daltons, or approximately 15,000 bases which encodes six main structural proteins. The genomic RNA is associated with the nucleocapsid (NP), phosphoprotein (P) and large (L) proteins. These macromolecules

form the transcriptive complex of the virus, which in turn is surrounded by a lipid bilayer membrane derived from the host cell. Embedded in the membrane are the haemagglutinin-neuraminidase (HN) and fusion (F) glycoproteins. Beneath the lipid bilayer is a shell of protein known as the matrix (M) protein, which is believed to interact with the transcriptive complex. The HN and F glycoproteins are associated with the host cell receptor during infection. The NP encapsidates the viral RNA together with the L protein which is thought to be the transcriptase, and a P protein with an unknown reason.

The genes encoding for the HN (EMBL/Gen Bank/DDBJ accession No.X70092), F (EMBL/Gen Bank/DDBJ accession No.AFO48763) and M (EMBL/Gen Bank/DDBJ accession No. AF060563) proteins of the NDV strain AF2240 have been completely sequenced by Tan *et al.* (1995), Salih *et al.* (2000) and Jemain, S.F.P. (1999) respectively. From the HN gene sequence of strain AF2240, it was quite clear that this strain is different from the other published NDV strains. The HN protein lacked the Arg (403) residue and contained 581 amino acids. At the time when the project was initiated, there was no information available on the coding sequences for the NP and P proteins of NDV strain AF2240. Therefore it remained a problem to prepare cDNA for the cloning of the NP and P genes of NDV.

The inventors have now successfully determined the nucleotide sequences encoding the NP and P proteins of NDV strain AF2240. The accession numbers for the genes encoding the NP and P proteins are EMBL/Gen Bank/DDBJ No. AF284646 and AF284647 respectively. The inventors had discovered that the proteins, in either non-fusion or fusion forms bearing the *myc* epitope and six residues of His at their carboxyl terminal end could be successfully produced in *E. coli* by means of recombinant DNA technologies. The NP and P proteins were expressed to a substantial level in the bacteria and can be recognised by chicken anti-NDV serum.

### Summary of invention

The present invention provides nucleotides encoding the full length NP and P polypeptides of Newcastle disease virus strain AF2240. Whereas the genome of NDV is of length approximately 15,000 nucleotides, it has been determined, by this invention, that the portion coding for the NP polypeptide is approximately 1470 nucleotides long and the

portion that codes for the P polypeptide is approximately 1188 nucleotides long. Accordingly, one aspect of the present invention provides for the coding regions of the nucleocapsid (NP) and phosphoprotein (P) genes of Newcastle disease virus strain AF2240. Both the nucleotide sequences are as listed below:

5 NP coding region

A primary use of the nucleotides as defined above is for the creation of plasmids using recombinant DNA technologies. The resulting recombinant molecule can then be introduced into an appropriate host. The plasmids thus created can be used to encode NP and P proteins. For expression of the NP and P proteins, any of the common expression  
 5 vectors, especially the bacterial vectors can be used. The usable bacterial hosts for the vectors include any of the conventional prokaryotic cells. In this invention, the bacterial host used was *Escherichia coli*. Accordingly, a further aspect of the present invention provides for a prokaryotic cell, such as for example a bacterial cell and in particular an *E. coli* cell containing the nucleotides as defined above for the production of NP and P  
 10 proteins.

The NP and P proteins, produced using recombinant plasmids in accordance with the present invention, can be in the fusion or non-fusion forms. In accordance with the embodiment of the present invention, it provides a method for producing the fusion and non-fusion forms of both the NP and P proteins of NDV virus strain AF2240 in an *E. coli*  
 15 system. The preferred method for producing the fusion and non-fusion forms of both the NP and P proteins of NDV virus strain AF2240 comprises culturing the transformed *E. coli* of the present invention on an appropriate medium to express the said nucleocapsid protein and phosphoprotein, and isolating and purifying the expressed fusion proteins from the cultures.

While the invention will now be described in connection with certain preferred  
 20 embodiments in the following experiments so that aspects thereof may be more fully understood and appreciated, it is not intended to limit the invention to these particular embodiments. On the contrary, it is intended to cover all alternatives, modifications and equivalents as may be included within the scope of the invention as defined by the  
 25 appended claims.

### Brief description of the figures

Figure 1 is a western blot of NDV nucleocapsid protein (NP) expressed by transformed *E. coli* TOP10 containing plasmid pTrcHis2-NP

Figure 2 is a western blot of NDV phosphoprotein (P) expressed by transformed *E. coli* TOP10 containing plasmid pTrcHis2-P  
 30

### Detailed description of the invention

The present invention was accomplished through the employment of the recombinant DNA techniques which comprises the amplification of the NP and P coding regions of NDV strain AF2240, the cloning of the genes into the expression vector, the production of the transformed *E. coli*, the cultivation of the transformant, the expression of the NP and P proteins and the purification of the expressed fusion proteins.

The NP and P coding regions of NDV strain AF2240 which had been cloned into the expression vector were prepared through reverse transcription-polymerase chain reaction (RT-PCR). Three primers were used for each gene, which consisted of one forward and two reverse primers as listed below:

#### For the amplification of the NP gene

NPf1 (20 mer): 5'- cct tct gcc aac atg tct tc -3' (Forward primer)

NPr1 (20 mer): 5'- tca ata ccc cca gtc ggt gt -3' (Reverse primer)

NPr2 (18 mer): 5'- ata ccc cca gtc ggt gtc -3' (Reverse primer)

#### For the amplification of the P gene

Pf1 (20 mer): 5'- atg gcc acc ttt aca gat gc -3' (Forward primer)

Pr1 (23 mer): 5'- taa tta gcc att tag tgc aag gc -3' (Reverse primer)

Pr2 (21 mer): 5'- gcc att tag tgc aag ggc ctt -3' (Reverse primer)

Incorporation of primers designated as NPf1 and NPr1 (for the NP gene), or Pf1 and Pr1 (for the P gene) during PCR had amplified gene products containing a stop codon at their 3' ends, while the presence of primers NPf1 and NPr2 (for the NP gene) or Pf1 and Pr2 (for the P gene) gave rise to genes without any no stop codon. For cloning and expression purposes, a commercially available expression vector, pTrcHis2 (Invitrogen, USA) containing the coding regions for the *myc* epitope and 6 His residues downstream of the multiple cloning site was used. After cloning of the respective coding regions of NP and P genes into the pTrcHis2 vector, they were subsequently introduced into a bacterial host *E. coli* TOP10. The resulting plasmid harbouring the NP gene was designated as pTrcHis2-NP while the other one with the P gene as an insert was denoted as pTrcHis2-P. Both the

NP and P proteins were expressed in *E.coli* TOP10 cells as non-fusion and fusion proteins. The latter forms contain the *myc* epitope and 6 His residues at their C termini. For protein identification, protein samples were analysed with SDS- PAGE and then followed by immunoblotting with the anti-NDV chicken serum and the anti-myc monoclonal antibody. The western blots for NP and P proteins are as shown in Figure 1 and Figure 2, respectively.

The expressed NP fusion protein was purified with affinity chromatography (nickel column), and was judged to be more than 90% pure by SDS-PAGE.

The nucleotide sequences of the NP and P genes were determined by the ABI PRISM automated sequencer, model 377. The recombinant plasmids, pTrcHis2-NP and pTrcHis2-P, were used as templates and the synthetic primers used in the sequencing reactions of the NP and P genes are as follows:

For the sequencing of the NP gene coding region

pTrcHis2F (21 mer): 5'- gag gta tat att aat gta tcg -3'  
 sNPf1 (21 mer): 5'- gac tca tac atc agg aac acc -3'  
 sNPf2 (21 mer): 5'- gat gag agc agt ggc gaa cag -3'  
 pTrcHis2R (18 mer): 5'- gat tta atc tgt atc agg -3'  
 sNPr1 (20 mer): 5'- tca ata ccc cca gtc ggt gt -3'  
 sNPr2 (21 mer): 5'- cta agt tgt aat acg tgg agc -3'  
 sNPr3 (21 mer): 5'- cca tcg atc tca aga aca tgc -3'

For the sequencing of the P gene coding region

pTrcHis2F (21 mer): 5'- gag gta tat att aat gta tcg -3'  
 sPf1 (21 mer): 5'- gtc gac ttt gtg cag gcg atg -3'  
 sPf2 (21 mer): 5'- gga cac tgt ccg tgc att gat -3'  
 pTrcHis2.R (18 mer): 5'- gat tta atc tgt atc agg -3'  
 sPr1 (21 mer): 5'- cca ggg tec aga att ttc atc -3'  
 sPr2 (22 mer): 5'- ggt gtg gat agc tgt ttg tct g -3'

Both the NP and P coding regions were sequenced from 5' to 3' direction and reversely from 3' to 5' direction.

Example I illustrates the recombinant DNA techniques employed in obtaining bacterial clones harbouring a plasmid containing inserts of NP and P coding cDNA for NDV genomic RNA, the nucleotide sequences of the NP and P genes, and also the expressed NP and P proteins.

## EXAMPLE I

### Virus Propagation

The stock of NDV strain AF2240 was originally obtained from the Veterinary Research Institute (VRI), Ipoh. The virus was grown in the allantoic cavity of 8 to 9 day-old chicken embryonated eggs according to the procedures of Blaskovic and Styk (1967). After 3 - 4 days of incubation at 37°C, the eggs were chilled overnight at 4°C. The allantoic fluid was then harvested and the presence of the viruses was determined by haemagglutination (HA) test. The allantoic fluid which showed positive reaction of HA test was then clarified by centrifugation at 6000 xg for 20 min at 4°C (Beckman, JA14 rotor, USA) to remove debris.

### Genomic RNA extraction

Total RNA was extracted using the Trizol LS reagent (Gibco BRL, USA). Briefly, 250 µl of the virus infected allantoic fluid was mixed with 750 µl Trizol LS reagent and incubated for 5 min at room temperature. After incubation, 100 µl of 1-bromo-3-chloropropane (BCP) (MRC, UK) was added and the mixtures were mixed vigorously for about 15 s and again incubated at room temperature for 10 min. The mixtures were phase separated by microcentrifuging at 13,000 xg for 15 min at 4°C (Jouan MR 1812, France). The RNA was then precipitated by adding 500 µl of isopropanol (Merck) to the aqueous phase and left at room temperature for 10 min. The precipitated RNA was microcentrifuged at 13,000 xg for 10 min and the pellet obtained was washed once with 75% (v/v) diethyl pyrocarbonate (DEPC) (Sigma, USA) treated ethanol (Hamburg). The pellet was dissolved in 20 µl of DEPC treated dH<sub>2</sub>O.

### **cDNA synthesis and amplification of nucleocapsid (NP) and phosphoprotein (P) genes by RT-PCR**

The amplification reactions were carried out in a programmed thermal cycler (MJ Research Inc. USA). Synthesis of the first strand cDNA was performed in a final volume of 30  $\mu$ l. The reaction mixture contained 0.4  $\mu$ M of each the forward and reverse primers, 0.2 mM deoxynucleoside triphosphate (MBI Fermentas, Inc. USA), 5 U of AMV reverse transcriptase (Promega, USA), 8 U of RNase inhibitor (Gibco BRL, USA), 1.5 mM of  $MgCl_2$  and 1x of reaction buffer (50 mM Tris-HCl, 15 mM  $(NH_4)_2SO_4$ , 0.1% Triton X-100). The mixture was incubated at 42°C for 30 min to synthesise the first strand of cDNA, and then 94°C for 3 min to inactivate the reverse transcriptase.

For the amplification of the respective NP and P genes, another 20  $\mu$ l of reaction mixture containing 1 U of DyNAzyme EXT DNA polymerase (FINNZYMES), 1.5 mM of  $MgCl_2$  and 1 x of reaction buffer was added to the top of the above cDNA mixture which was held at 94°C in the thermal cycler. The PCR profile for the amplification of NP gene comprising denaturation at 94°C for 30 s, annealing at 55°C for 50 s and extension at 72°C for 1 min for a total of 30 cycles. To ensure a complete synthesis of the PCR product, the extension step at 72°C was prolonged for 7 min after the last cycle. The PCR profile for the amplification of P gene was basically similar to that of NP gene, except the annealing step was carried out at 55°C for 30 s.

### **Purification of the amplified PCR products**

A total of 40  $\mu$ l of the amplified PCR product was analysed on 1% TAE agarose gel. After the staining with ethidium bromide, the band with the correct size was excised from the gel and purified with the Wizard PCR Preps DNA Purification System (Promega, USA) according to the manufacturer's procedures. After purification, 5  $\mu$ l of the PCR product was again analysed with agarose gel electrophoresis to determine the recovery of the PCR product, which would be used in TA cloning.

### TOPO TA Cloning of NP and P genes

Four  $\mu\text{l}$  of the purified NP or P DNA fragments carrying an A overhang at their 3' ends was mixed with 1  $\mu\text{l}$  of the pTrcHis2 TOPO expression vector (Invitrogen, USA) and the ligation reaction was carried out at room temperature (25°C) for 5 min to form the desired recombinant plasmid.

### Transformation

For transformation, 5  $\mu\text{l}$  of the ligation mixture was added to 50  $\mu\text{l}$  of TOP10 *E. coli* competent cells (Invitrogen, USA). The transformation mixture was incubated on ice for 30 min and the cells were heated at 42°C for 30 to 60 s. This was followed by the adding of 250  $\mu\text{l}$  SOC medium (2% trypton, 0.5% yeast extract, 10 mM NaCl, 2.5 mM KCl, 10 mM  $\text{MgCl}_2$ , 10 mM  $\text{MgSO}_4$ , 20 mM glucose) and the incubation of the reaction mixture at 37°C for 30 to 60 min with shaking at 250 rpm. Thirty-50  $\mu\text{l}$  of the transformation mixture was spread on a LB plate containing 50  $\mu\text{g/ml}$  ampicillin and 0.5% of glucose, and the plates were then incubated overnight at 37°C.

### Screening for positive clones

Ten single colonies were randomly chosen and cultured overnight in 3 to 5 ml of LB medium containing 50  $\mu\text{g/ml}$  ampicillin and 0.5% glucose. Plasmid DNA was isolated by using the alkaline lysis method and the orientation of the insert in the positive clones was confirmed by PCR.

### Protein expression

The identified positive clones were cultured overnight in LB medium containing 50  $\mu\text{g/ml}$  ampicillin. The next day, 10 ml of LB medium containing 50  $\mu\text{g/ml}$  ampicillin was inoculated with 0.2 ml of the overnight culture and incubated at 37°C with shaking at 250 rpm. Once the cells reached the optical density of 0.6 to 0.8 at  $A_{600}$ , 1 mM IPTG was

added into the culture and continued shaking for 3 to 5 hours. The cells were harvested from the culture by centrifugation and then subjected to polyacrylamide gel electrophoresis (SDS-PAGE).

### SDS-PAGE and western blotting

The cell pellets (from 1 ml culture solution) were resuspended in 50 to 100  $\mu$ l of 1X SDS-PAGE sample buffer and boiled for 10 min. Five to 10  $\mu$ l of the sample was loaded onto 12% SDS-PAGE gel and electrophoresed for 70 to 80 min at 32 volt. The proteins on SDS-PAGE gel were then electro-transferred onto a nitrocellulose membrane for 1 h. Western blotting was carried out by blocking the membrane first with skim milk for 1 h to saturate unoccupied regions on the membrane. This was followed by adding the anti-NDV chicken serum or anti-*myc* monoclonal antibody (for fusion protein) onto the membrane and this was shaken for 1 h at room temperature. The membrane was then washed four times with TTBS washing solution (TBS containing 0.5% Tween 20), 5 to 10 min for each wash to remove the unbound antibodies. After washing, peroxidase-labelled antibody was added to react with the primary antibody and left shaking for another 1 h. The membrane was further washed four times with TTBS solution, each for 5 to 10 min, and lastly BCIP/NBT solution was added as substrate for the peroxidase. The molecular weight of NP and P proteins was about 55 kDa while the fusion form for both the NP and P proteins gave rise to an apparent molecular weight of about 60 kDa.

### Purification of NP fusion protein using ProBond Column

Two hundred  $\mu$ l of LB medium containing 50  $\mu$ g/ml ampicillin was cultured with 2 ml of overnight culture of transformant harbouring plasmid pTrcHis2-NP (carrying the NP insert without a stop codon), and the cells were grown to an OD<sub>600</sub> of 0.6 to 0.8. Protein expression was then induced by adding 1 mM IPTG and the cells were grown for another 5 h. The cells were harvested by centrifugation at 2000  $\times$ g for 15 min at 4°C. The cell pellet was first resuspended in 10 ml of binding buffer (500 mM NaCl, 20 mM NaH<sub>2</sub>PO<sub>4</sub>, pH 7.8), then 100  $\mu$ g/ml of lysozyme was added and incubated for 15 min on ice. The cells were lysed by sonication until the cell lysate is no longer viscous. The cell lysate was then treated with RNase and DNase I, both at a concentration of 5  $\mu$ g/ml for 15 min at 30°C. The cell lysate was then centrifuged at 10,000  $\times$ g for 20 min to remove all the cell

debris. The supernatant was collected and passed through a 0.45  $\mu\text{m}$  filter. This cell lysate was incubated with the ProBond resin (Invitrogen, USA) for 30 min and then allowed to drip through the resin. The column was washed with 10 ml of washing buffer (50 mM Imidazole, 500 mM NaCl, 20 mM  $\text{NaH}_2\text{PO}_4$ , pH 6.0), and the proteins were then eluted with 5 ml of elution buffer (500 mM Imidazole, 500 mM NaCl, 20 mM  $\text{NaH}_2\text{PO}_4$ , pH 6.0). The elute was collected as 1 ml fractions. Samples from each fractions were analysed on 12% SDS-PAGE to check the purity of the protein.
